

# **Project Planning Report for a Program of Utilities Infrastructure Renewal Projects for the St. George Campus**

## **I Background Information**

The constant increase of research activities and academic growth on campus has put a strain on the existing electrical distribution system that supports both the laboratories themselves and the heating and cooling systems needed to keep them operating. In May 2008, a report to the Planning and Budget Committee (which was eventually approved at Governing Council) noted that the southeast quadrant of the campus urgently needed new power sources. That first report concentrated on re-feeding the Wallberg Building from Toronto Hydro, a project which is now complete. It also noted that a subsequent plan would be drafted to address the same issue at the Medical Sciences Building.

The Medical Sciences Building contains a central chiller plant serving 15 surrounding buildings including the Terrence Donnelly Centre for Cellular Bio-molecular Research, the Leslie Dan Pharmacy Building, the Tanz Neuroscience Building, the Fitzgerald Building and other academic and administrative buildings. The portfolio of facilities served by this plant has grown without always a corresponding increase in production capacity. During the past two summers during periods of high heat and humidity, the chillers have not been able to keep up with the cooling requirements of the area, resulting in warmer, more humid space conditions. While this may be an acceptable and understandable situation during heat waves in other functional type buildings, it is not acceptable in laboratory buildings which specialize in medical research. Therefore, another chiller will need to be added to the Medical Sciences central plant to correct this problem.

Unfortunately, a new chiller cannot simply be added to the existing system as it now stands. Spare electrical capacity is not available at the Medical Sciences Building. At the same time, spare electrical capacity is now unavailable in both the Sandford Fleming Building and the Galbraith Building. In fact, the electrical feeder loop that supplies the south east area of the campus is already overloaded. Should there be a failure of any segment of the loop the normal procedure is to feed power to a building in the reverse direction, bypassing the failed segment. This allows the power to be quickly restored through simple switching. As it stands now, a feeder failure would necessitate load shedding in order to partially supply the buildings while a full repair is implemented.

In addition, building projects either now in the planning or construction stage such as the Rotman expansion or on the horizon such as the developments at Site #12 will tax the remaining spare steam production capacity requiring improvements to be made in order that these facilities may be fed from the efficient district energy system that the University has developed.

## **II. Impact on the Academic Plan**

Failure to deal with the capacity shortage of heating, cooling and electricity would mean that certain new buildings would not benefit from efficiencies inherent in district energy systems, and existing facilities with expanding programs would not be served adequately. If power is not re-supplied to Medical Sciences, the growing research program in the southeast quadrant of the campus can not be accommodated and the southeast area would suffer from inadequate cooling capacity. New buildings projected for the area like Enabling Technologies in the longer term would have to have their own local cooling systems instead of being able to connect to a centralized system which saves equipment costs and valuable floor area in the buildings.

## **III. Project Description**

### **(a) New electrical feed to Medical Sciences, Sandford Fleming and Galbraith buildings**

The Medical Sciences Building and the Sandford Fleming Building are both fed from Loop 1 on the 13,800 volt system. The Galbraith Building is fed from Loop 6 on the 4,160 volt system. A plan has been proposed to re-feed the Medical Sciences Building with a new 13,800 volt feeder in a new buried duct bank from the central station at Russell Street. This will provide the Medical Sciences Building with full capacity from the loop feeders without de-rating due to heat build-up in the ducts. The Galbraith Building will then be re-fed from the Sandford Fleming Building which is fed from the existing 13.8kV loop feeders.

The capacity available at the University's central station is the result of re-feeding certain large buildings such as the Bahen Centre for Information Technology and the Wallberg/Pratt Building directly from Toronto Hydro to deal with shortfalls on the distribution feeder system.

The implementation of this plan will entail burying a 13.8 kV duct bank from Russell and Huron, across St. George Street to the Medical Sciences Building to create a new loop. Sandford Fleming will remain in the existing loop and sub-feed the Galbraith Building. Since the Galbraith Building has been fed at a different voltage until now, a new substation with new transformers would have to be located there, requiring an allocation of space and re-work of the building components. Re-work of the feeders and high voltage equipment at the Sandford Fleming end of the system would also have to take place. Allocation of space and re-work of the high voltage switchboard is required to accommodate additional switchgear in order to sub-feed Galbraith's other loads.

**(b) New chiller for the southeast quadrant of campus**

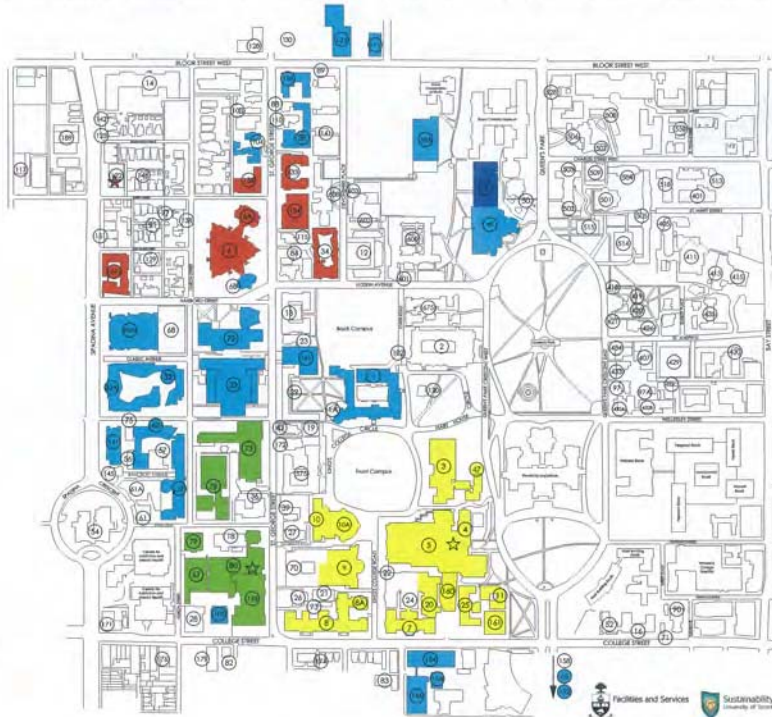

The chiller plant housed in the Medical Sciences Building feeds chilled water for air conditioning to 15 buildings in the area (Gerstein, Canadiana, McMurrich, Tanz, Leslie Dan Pharmacy, Fitzgerald, CCBR, Rosebrugh, Mining, Wallberg, Pratt, Sandford Fleming, Simcoe Hall, Convocation Hall and MSB). Loads from steadily growing research, academic and administrative activities in many of these buildings have increased to the point where it is not possible to maintain proper cooling and dehumidification in many of the facilities during hot periods of the summer. It is inevitable that this trend will continue, putting critical research at risk – there is now no effective standby capacity to cover potential breakdowns of equipment.

It is proposed to augment the capacity in the plant with a new 2,500 Rton chiller. There is sufficient space in the MSB chiller room for this equipment. As well, cooling tower and pumping capacity will be augmented.

**It is important to note that this project can only be initiated if the companion project – the electrical re-feed of MSB, Sandford Fleming and Galbraith – is completed.**

**(c) Increasing heat production at the Central Steam Plant**

The Central Steam Plant on Russell Street provides heat to 85% of campus buildings as well as the Trinity, St. Michael's and Victoria College campuses. The plant consists of 4 large boilers as well as a waste heat boiler that uses heat from the cogeneration operation and a direct contact heat recovery system that further gleans heat from the exhaust gases that would otherwise be wasted up the chimney. While the total capacity of this equipment is sufficient to heat the space planned for development on campus, various bottlenecks in the system such as the capacity to produce treated feed water, and the limited quantity of oil we have as a standby fuel for periods when natural gas is not available prevent the full boiler capacity from being used.

While the heat distribution system returns more than 90% of its condensate to the plant conserving the residual heat, this water must be processed in a de-aerator. The existing equipment is operating at its maximum. The water treatment facility must be expanded to allow additional boiler capacity to be exploited.

The Technical Standards and Safety Authority has indicated that the 405,000 litre underground concrete oil storage tanks that serves the plant will no longer be acceptable in its current form. This problem can be solved by installing independent metal or plastic tanks inside the concrete vault of the old tanks. This will allow us to keep sufficient oil stored on site to cover periods when natural gas is not available, either from an emergency in the system, or when Enbridge exercises its right to curtail the gas supply as part of the terms of the lucrative interruptible contract that saves the University about \$1 million per year.

**IV. Special Considerations**

Landscaping

Routing cable under university roads and paved or landscaped areas must be performed by tunneling or open cut excavations with restoration of the area to the original condition included in the project.

**V. Resource Implications**

Capital cost estimate

The Total Project Cost Estimate for this program of projects can be summarized as:

Re-feed power to Medical Sciences, Sandford Fleming and Galbraith	5,000,000
Additional chiller in southeast chiller plant	3,550,000
Increase steam plant capacity	2,600,000
Construction financing	<u>82,000</u>
Total	\$11,232,000

(See Appendix A for detailed breakdown)

### Operating Costs

Increased power and natural gas costs will be incurred by the University as a result of the research performed in new labs and buildings and will be captured in the reports for those facilities.

## **VI. Funding Sources**

Required funds will be obtained by borrowing internally for a period of 25 years with the principal and interest paid from the annual utilities budget. The cost of the annual principal and interest payments would be added to the central utilities budget and spread equitably across the St. George divisions in accordance with the new budget model.

In addition, an annual contribution of \$1,000,000 will be made in each of the first five years from the utilities infrastructure renewal reserve fund.

Should there be surpluses available in the central utilities budget due to energy purchases less than budget, these surpluses will be put towards paying down the principal.

Assuming current interest rates for a loan with a 25 year term, payments will be \$720,000 per year.

## **VII. Schedule**

The increased capacity provided by this work is required as soon as possible in order to allow certain research initiatives to proceed without inconvenient scheduling of academic activities to prevent overloads. It is proposed that the chiller project be initiated after the start of the electrical re-feed project in order to provide the required lead time.

A proposed project schedule is attached as Appendix B.

## **VIII. Recommendations**

It is recommended that the Planning and Budget Committee recommend to the Academic Board:

- THAT the Utilities Infrastructure Renewal program of projects be approved, at a total cost not to exceed \$11.232 million, with funding as follows:
  - \$5 million from utilities infrastructure renewal funds and the balance a loan to be repaid by increasing the annual utilities budget by \$720,000.

**Appendices:**

- A. Total Project Costs Estimates
- B. Project timeline
